

First you need to link your project with **JS SDK** by adding it to your project Workspace. Open folder with SDK, find file **jasperserver-mobile-sdk-ios.xcodeproj** and drag it to your **Project navigator**.

Now you need to configure some additional settings and add Frameworks to build configuration. Click on the project header in **Project navigator** (**JasperServer SDK Installation** in this example). Open tab **Build Settings** and search “**Header Search Paths**” section. Double click on it to open panel for adding flags. Add “**/usr/include/libxml2**” flag and close panel (simply by click outside of panel)

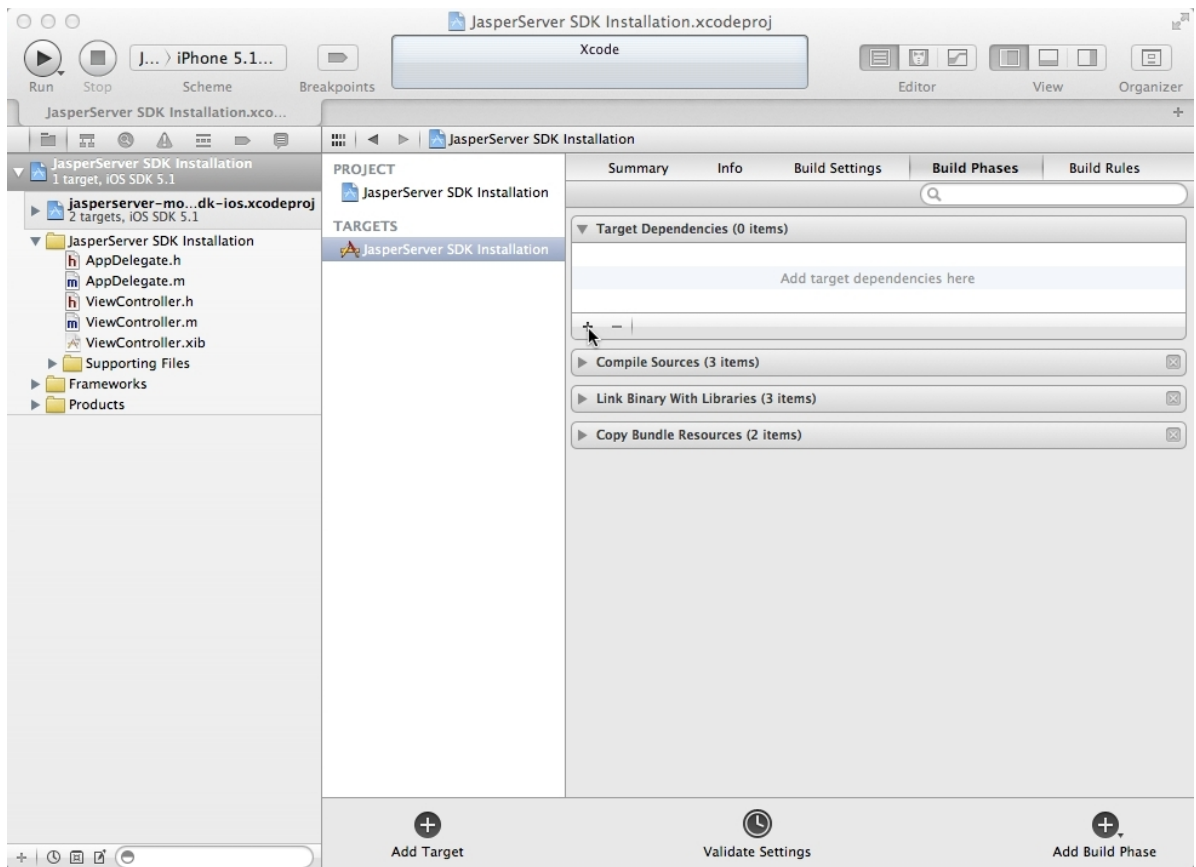

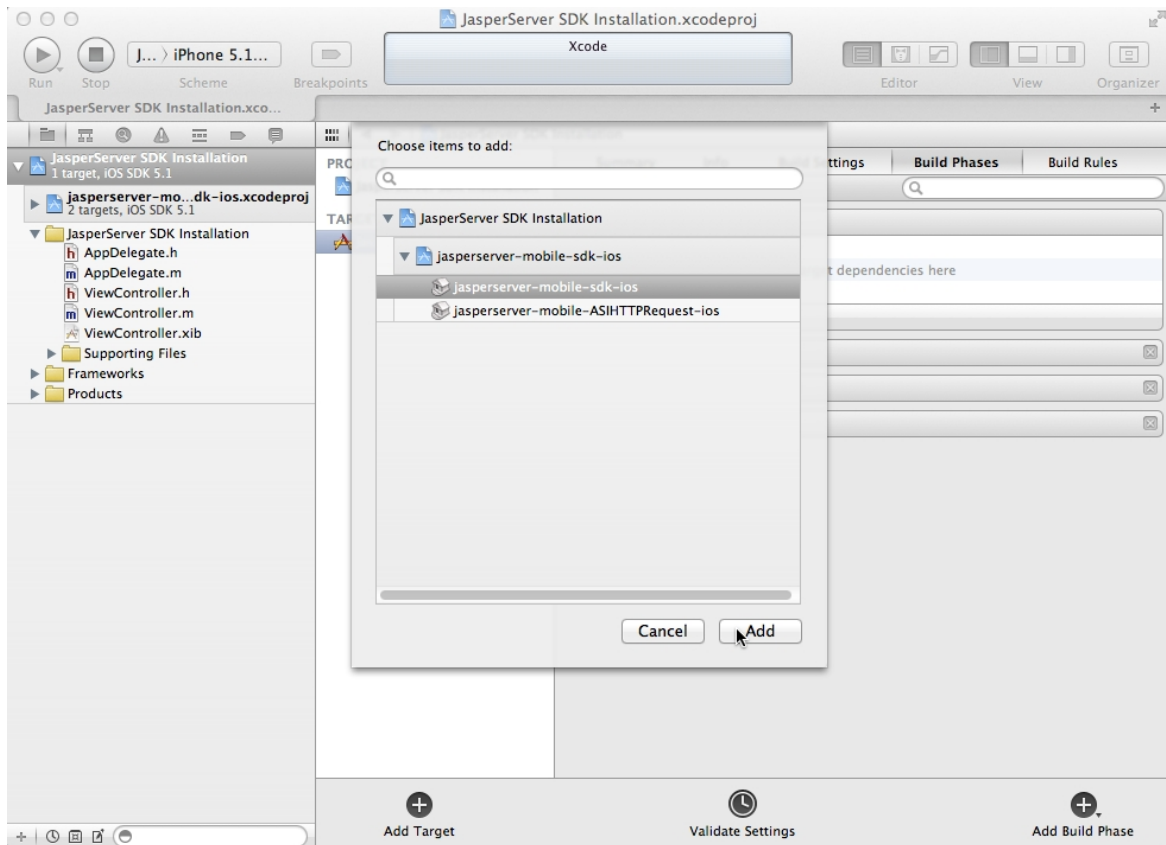

After configuring **Header Search Paths** you need to setup dependencies. Open tab **Build Phases** and

expand **Target Dependencies** section. Hit **+** button, select **jasperserver-mobile-sdk-ios** target and hit **add**.

Expand **Link Binary With Libraries** section. Same as previous steps add **jasperserver-mobile-sdk-ios.a** compiled library and all next required frameworks:

1. **CFNetwork**
2. **SystemConfiguration**
3. **MobileCoreService**
4. **libxml2.dylib**
5. **libz.dylib**

You have now completed installation of **JS SDK** into your application. To verify the installation, open up your App Delegate and add an import of the **JSCClient** header:

```
#import <jasperserver-mobile-sdk-ios/JSCClient.h>
```

Build your project and verify build output. Project should build without any issues. Congratulations! You have successfully finished **JS SDK** installation!
